Courthouse Spatial Graph

These plots visualize a courthouse as a dual graph derived from its 3D geometry. Each room is reduced to a single vertex placed at its interior, and edges connect rooms that share a door or a window, producing a network that captures how the building is actually navigated rather than just how it looks.

Vertices are color-coded by program: yellow for public spaces, red for jury areas, blue for judge zones, and black for prisoner circulation. Doors follow the same color logic of the rooms and windows appear in cyan, with both rendered smaller than the room nodes so the room-to-room structure stays legible.

The top view (image 1) reveals the building's strong bilateral symmetry and the central public hub from which corridors radiate, while the axonometric view (image 2) shows how the four programs are stacked and segregated across the plan, judges and prisoners kept on dedicated paths, the public funneled through the core, and jury rooms tucked between them. Together the graphs make explicit the adjacency logic that governs movement and separation in a courthouse.
